Sickness in Salonica: my first, worst, and most successful clinical trial-1941.

". . . I recruited 20 young prisoners . . . I gave them a short talk about my medical hero James Lind and they agreed to co-operate in an experiment. I cleared two wards. I numbered the 20 prisoners off: odd numbers to one ward and evens to the other.

Each man in one ward received two spoonfuls of yeast daily. The others got one tablet of vitamin C from my "iron" reserve. The orderlies co-operated magnificently . . . They controlled fluid intake and measured frequency of urination.

. . . There was no difference between the wards for the first two days, but the third day was hopeful, and on the fourth the difference was conclusive . . . there was less oedema in the "yeast" ward. I made careful notes of the trial and immediately asked to see the Germans."

A. L. Cochrane (Br Med J 1984; 289: 1726-7)

"It could be argued that the trial was randomised and controlled, although this last was somewhat inadequate. In those early days, when the randomised controlled trial was little known in medicine, this was something of an achievement."

BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 30 1948

STREPTOMYCIN TREATMENT OF PULMONARY TUBERCULOSIS

A MEDICAL RESEARCH COUNCIL INVESTIGATION

The following gives the short-term results of a controlled investigation into the effects of streptomycin on one type of pulmonary tuberculosis. The inquiry was planned and directed by the Streptomycin in Tuberculosis Trials Committee, composed of the following members: Dr. Geoffrey Marshall (chairman), Professor J. W. S. Blacklock, Professor C. Cameron, Professor N. B. Capon, Dr. R. Cruickshank, Professor J. H. Gaddum, Dr. F. R. G. Heaf, Professor A. Bradford Hill, Dr. L. E. Houghton, Dr. J. Clifford Hoyle, Professor H. Raistrick, Dr. J. G. Scadding, Professor W. H. Tytler, Professor G. S. Wilson, and Dr. P. D'Arcy Hart (secretary). The centres at which the work was carried out and the specialists in charge of patients and pathological work were as follows:

Brompton Hospital, London.—Clinician: Dr. J. W. Crofton, Streptomycin Registrar (working under the direction of the honorary staff of Brompton Hospital); Pathologists: Dr. J. W. Clegg, Dr. D. A. Mitchison.

Colindale Hospital (L.C.C.), London.—Clinicians: Dr. J. V. Hurford, Dr. B. J. Douglas Smith, Dr. W. E. Snell; Pathologists (Central Public Health Laboratory): Dr. G. B. Forbes, Dr. H. D. Holt.

Harefield Hospital (M.C.C.), Harefield, Middlesex.—Clinicians: Dr. R. H. Brent, Dr. L. E. Houghton; Pathologist: Dr. E. Nassau.

Bangour Hospital, Bangour, West Lothian.—Clinician: Dr. I. D. Ross; Pathologist: Dr. Isabella Purdie.

Killingbeck Hospital and Sanatorium, Leeds.—Clinicians: Dr. W. Santon Gilmour, Dr. A. M. Reevie; Pathologist: Professor J. W. McLeod.

Northern Hospital (L.C.C.), Winchmore Hill, London.—Clinicians: Dr. F. A. Nash, Dr. R. Shoulman; Pathologists: Dr. J. M. Alston, Dr. A. Mohun.

Sully Hospital, Sully, Glam.—Clinicians: Dr. D. M. E. Thomas, Dr. L. R. West; Pathologist: Professor W. H. Tytler.

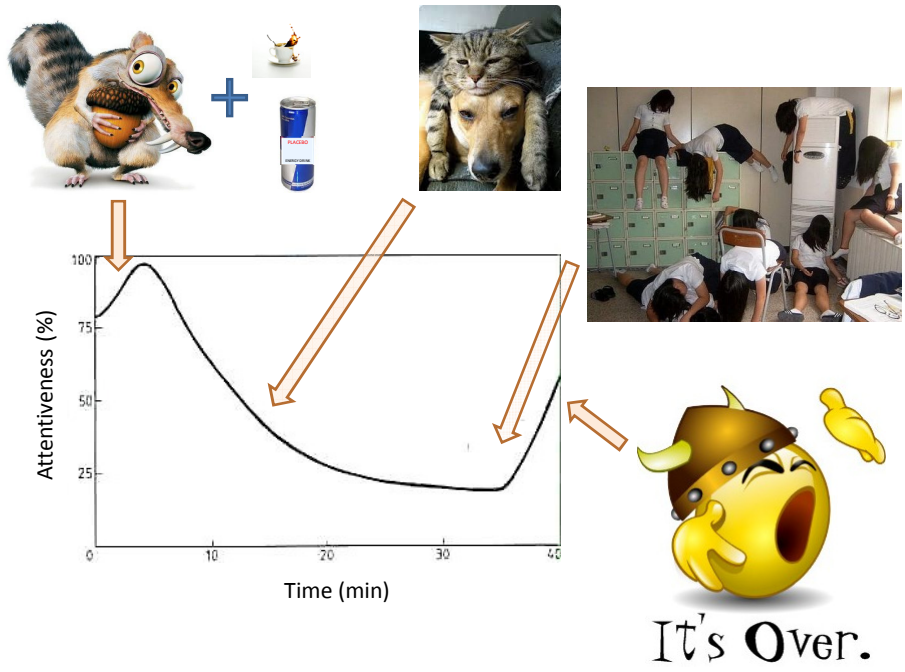
The clinicians of the centres met periodically as a working subcommittee under the chairmanship of Dr. Geoffrey Marshall; so also did the pathologists under the chairmanship of Dr. R. Cruickshank. Dr. Marc Daniels, of the Council's scientific staff, was responsible for the clinical co-ordination of the trials, and he also prepared the report for the Committee, with assistance from Dr. D. A. Mitchison on the analysis of laboratory results. For the purpose of final analysis the radiological findings were assessed by a panel composed of Dr. L. G. Blair, Dr. Peter Kerley, and Dr. Geoffrey S. Todd.

Introduction

When a special committee of the Medical Research Council undertook in September, 1946, to plan clinical trials of streptomycin in tuberculosis the main problem faced was that of investigating the effect of the drug in pulmonary tuberculosis. This antibiotic had been discovered two years previously by Waksman (Schatz, Bugie, and Waksman, 1944); in the intervening period its power of inhibiting

if based on adequately controlled clinical trials (Hinshaw and Feldman, 1944). The one controlled trial of gold treatment (and the only report of an adequately controlled trial in tuberculosis we have been able to find in the literature) reported negative therapeutic results (Amberson, McMahon, and Pinner, 1931). In 1946 no controlled trial of streptomycin in pulmonary tuberculosis had been undertaken in the U.S.A. The Committee of the Medical Research Council

- The problem…

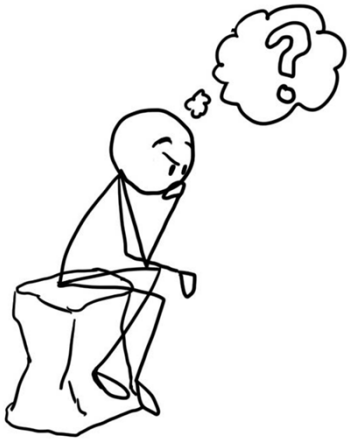


Engage your audience

- People respond to people. Rarely will you hold the attention of your audience through content alone.
- To engage the audience you need to interact with them, share your warm personality and gentle sense of humour and invite them to participate in some way.

http://www.skillsworkshop.net/a1.html

Why is this talk important to you?



You are here because?....

A. Part of the MSc – but no intention of teaching
B. You've never taught critical appraisal before but want to
C. You already teach some but want to pick up new skills or refine yours
D. You already teach it to the highest level and came to share some skills with others
E. You made a terrible mistake on the application form and thought this was a weeks course on the History of Ancient and Medieval architecture….

CEBM

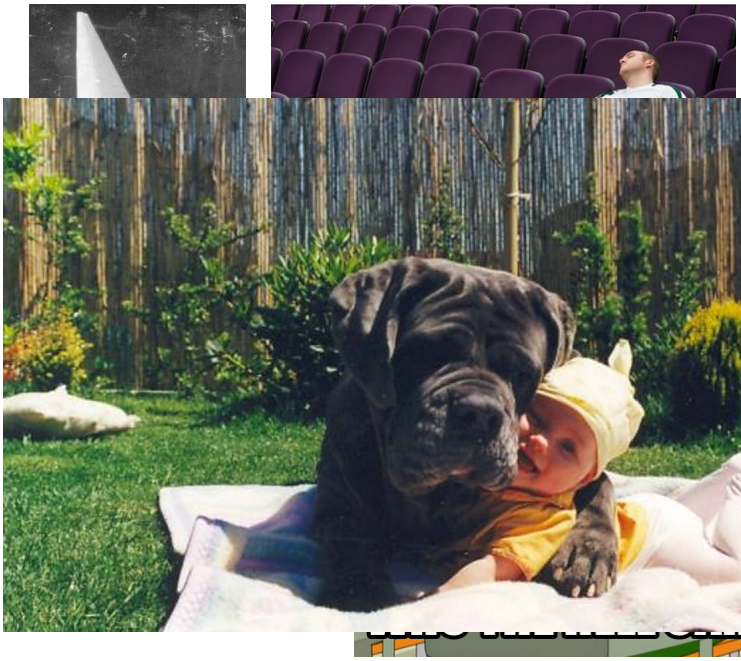
Know your audience

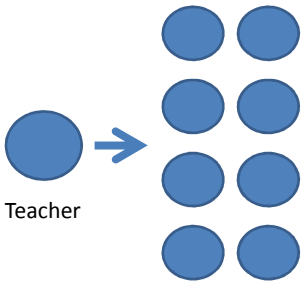
- Who are you teaching critical appraisal to?
- What are your learners objectives?
- Why are they here?

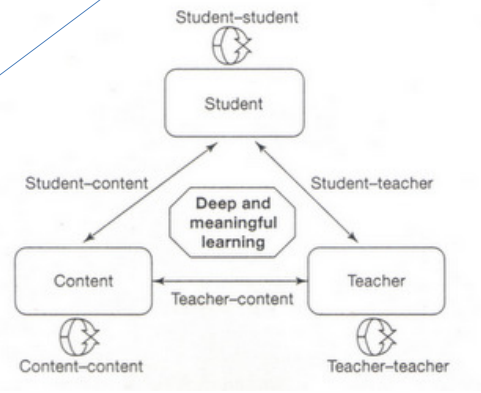


CEBM
CENTRE FOR EVIDENCE-BASED MEDICINE

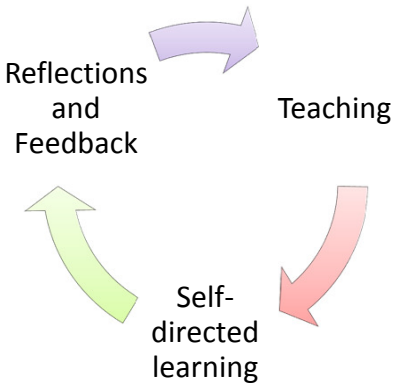
Try and create a safe environment

Models of teaching





Teaching-Feedback cycle



- Specific tools…content

What's so special about RCTs?

- most rigorous way of determining:
  - a cause-effect relation exists between treatment and outcome and
  - for assessing the cost effectiveness of a treatment
- distributing the characteristics of patients that may influence the outcome randomly between the groups-no systematic differences between intervention groups

What's so special about RCTs?

- patients and trialists should remain unaware of which treatment was given until the study is completed to avoid influencing the result
- both arms treated identically except for the intervention of interest – estimating the size of the difference in predefined outcomes between intervention groups

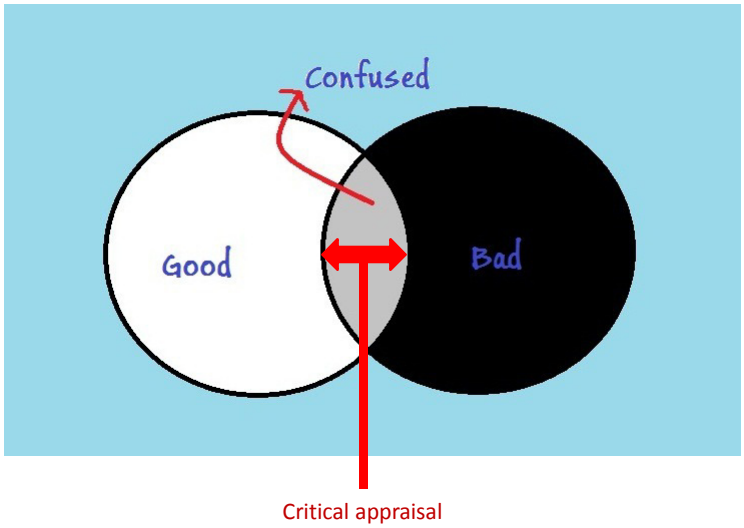
So are RCTs the gold standard for evidence?

.....depends

Limitations of RCTs

- Excellent vs Poor RCTs – quality varies
  - Impact on interpretation of result (external validity)?
- Expensive and time consuming
  - £250k - £millions over 2-5 years+
- May not always be the right study design to answer that question

Types of evidence



Critical appraisal….

…is like being a detective.

You need the skills to think broadly and detect the flaws that might distract you from finding the true answer.

Risk of Bias – internal validity

- The degree to which the result is skewed away from the truth
- Causal inferences from randomised trials can, however, be undermined by flaws in design, conduct, analyses, and reporting
- leading to underestimation or overestimation of the true intervention effect

Confounding factors

- Other patient features/causal factors, apart from the one being measured, that can affect the outcome of the study e.g..

Internal validity

- extent to which observed treatment effects can be ascribed to differences in treatment and not confounding, thereby allowing the inference of causality to be ascribed to a treatment.[1]
- Systematic error (bias) could threaten the internal validity of trials, and all efforts should be made to minimise these in the design, conduct, and analysis of studies.[2]

1. http://www.bmj.com/content/344/bmj.e1004
2. http://www.ncbi.nlm.nih.gov/pubmed/18728521

Types of bias

Type of bias	Description
Selection bias	Systematic differences between baseline characteristics of the groups that are compared.
Performance bias	Systematic differences between groups in the care that is provided, or in exposure to factors other than the interventions of interest
Attrition bias	Systematic differences between groups in withdrawals from a study
Detection bias	Systematic differences between groups in how outcomes are determined
Reporting bias	Systematic differences between reported and unreported findings

Abstract

Objective To investigate the effectiveness of facilitated physical activity as an adjunctive treatment for adults with depression presenting in primary care.

Design Pragmatic, multicentre, two arm parallel randomised controlled trial.

Setting General practices in Bristol and Exeter.

Participants 361 adults aged 18-69 who had recently consulted their general practitioner with symptoms of depression. All those randomised had a diagnosis of an episode of depression as assessed by the clinical interview schedule-revised and a Beck depression inventory score of 14 or more.

Interventions In addition to usual care, intervention participants were offered up to three face to face sessions and 10 telephone calls with a trained physical activity facilitator over eight months. The intervention was based on theory and aimed to provide individually tailored support and encouragement to engage in physical activity.

Main outcome measures The primary outcome was self reported symptoms of depression, assessed with the Beck depression inventory at four months post-randomisation. Secondary outcomes included use

−0.54 (95% confidence interval −3.06 to 1.99; P=0.68). Similarly, there was no evidence that the intervention group reported a change in mood by the eight and 12 month follow-up points. Nor was there evidence that the intervention reduced antidepressant use compared with usual care (adjusted odds ratio 0.63, 95% confidence interval 0.19 to 2.06; P=0.44) over the duration of the trial. However, participants allocated to the intervention group reported more physical activity during the follow-up period than those allocated to the usual care group (adjusted odds ratio 2.27, 95% confidence interval 1.32 to 3.89; P=0.003).

Conclusions The addition of a facilitated physical activity intervention to usual care did not improve depression outcome or reduce use of antidepressants compared with usual care alone.

Trial registration Current Controlled Trials ISRCTN16900744.

Introduction

Depression is one of the most common reasons for consulting a general practitioner within the United Kingdom, and its associated economic burden is considerable.[1] Although antidepressants are effective, many patients and healthcare professionals would like other options to be available as an alternative or adjunct to drug therapy.[2] Some evidence[3] shows

Exercise does little to help the symptoms of depression, new study finds

By SUZANNAH HILLS

PUBLISHED: 08:23, 6 June 2012 | UPDATED: 11:01, 8 June 2012

Comments (10) | Share | +1 0 | Tweet 16

Exercise does little to help alleviate the symptoms of depression, a new study has found.

The findings contrast with current clinical guidance which recommends exercise to help those suffering from the mental illness that affects one in six adults in Britain at any one time.

But research published in the British Medical Journal suggests that doing a physical activity combined with usual treatment did not reduce symptoms of depression more than the treatment alone.

Assessing risk of bias for an RCT

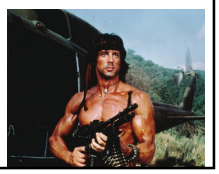
Critical Appraisal for Therapy Articles

THERAPY STUDY: Are the results of the trial valid? (Internal Validity)
What question did the study ask?
Patients –
Intervention -
Comparison -
Outcome(s) -

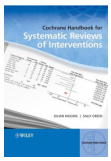
1a. R- Was the assignment of patients to treatments randomised?	
What is best?	Where do I find the information?
Centralised computer randomisation is ideal and often used in multi-centred trials. Smaller trials may use an *independent* person (e.g, the hospital pharmacy) to "police" the randomization.	The ***Methods*** should tell you how patients were allocated to groups and whether or not randomisation was concealed.
This paper: Yes ☐ No ☐ Unclear ☐ *Comment:*	
1b. R- Were the groups similar at the start of the trial?	
What is best?	Where do I find the information?
If the randomisation process worked (that is, achieved comparable groups) the groups should be similar. The more similar the groups the better it is. There should be some indication of whether differences between groups are statistically significant (ie. p values).	The ***Results*** should have a table of "Baseline Characteristics" comparing the randomized groups on a number of variables that could affect the outcome (ie. age, risk factors etc). If not, there may be a description of group similarity in the first paragraphs of the ***Results*** section.
This paper: Yes ☐ No ☐ Unclear ☐ *Comment:*	
2a. A – Aside from the allocated treatment, were groups treated equally?	
What is best?	Where do I find the information?
Apart from the intervention the patients in the different groups should be treated the same, eg., additional treatments or tests.	Look in the ***Methods*** section for the follow-up schedule, and permitted additional treatments, etc and in ***Results*** for actual use.
This paper: Yes ☐ No ☐ Unclear ☐ *Comment:*	
2b. A – Were all patients who entered the trial accounted for? – and were they analysed in the groups to which they were randomised?	
What is best?	Where do I find the information?
Losses to follow-up should be minimal – preferably less	The ***Results*** section should say how many patients were

RRAMMbo tool – Risk of Bias

		Type of bias
Recruitment	Were the subjects representative of the target population?	Selection bias Other sources of bias
Randomisation **A**llocation	How was randomisation carried out? Was allocation concealed?	Selection bias
Maintenance	Were the groups equal at the start? And maintained through equal management and f/u?	Performance bias Attrition bias
Measurement- **B**linding	Were the outcomes measured with blinded assessors/participants	Performance bias
Objective outcomes (Measurement)	Were there differences in how outcomes were determined	Detection bias



Selection bias



- systematic differences between baseline characteristics of the groups
- Adequate randomisation
  - 1) Sequence generation
  - 2) Allocation concealment

Sequence generation (selection bias)

Low risk of bias

- random number table
- Using a computer random number generator
- Coin tossing
- Shuffling cards or envelopes
- Throwing dice
- Drawing of lots

High risk of bias

- Sequence generated by a a non-random component e.g
  - odd or even date of
  - birth date (or day) of admission
  - hospital or clinic record number
- judgement of the clinician
- preference of the participant
- availability of the intervention

Allocation concealment (selection bias)

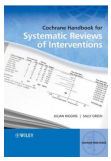
Low risk

- Central allocation (including telephone, web-based and pharmacy-controlled randomization
- Sequentially numbered drug containers of identical appearance
- Sequentially numbered, opaque, sealed envelopes.

High risk

- Alternation or rotation
- open random allocation schedule (e.g. a list of random numbers)
- envelopes were unsealed or non-opaque

Performance bias



- Systematic differences between groups in the care that is provided, or in exposure to factors other than the interventions of interest.
- Blinding of participants, personnel and outcome assessors

Blinding (Performance bias)

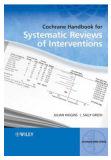
Low risk of bias

- No blinding, but outcome and the outcome measurement are not likely to be influenced
- Blinding of participants *and* personnel
- blinding of participants *or* personnel but outcome assesment unlikely to have been affected

High risk of bias

- No blinding or incomplete blinding, and the outcome or outcome measurement is likely to be influenced by lack of blinding
- Blinding of key study participants and personnel attempted, but likely that the blinding could have been broken
- No blinding

Attrition bias



- Systematic differences between groups in withdrawals from a study.
- **Attrition** refers to situations in which outcome data are not available
- **Exclusions** refer to situations in which some participants are omitted from reports of analyses, despite outcome data being available to the trialists.

Incomplete reporting (Attrition bias)

Low risk of bias

- No missing outcome data
- Reasons for missing outcome data unlikely to be related to true outcome
- Methodology ITT

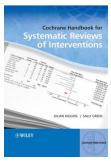
High risk of bias

- Reason for missing outcome data likely to be related to true outcome,
- "As-treated' analysis done with substantial departure of the intervention received from that assigned at randomization

Intention to treat (ITT)

- participants in trials should be analysed in the groups to which they were randomized, regardless of whether they received or adhered to the allocated intervention.
- 2 issues:
  - estimate the effects in practice
    - Not a subgroup who adhere to the intervention
    - "Per protocol" can overestimate effects
  - Loss to follow up
    - ITT ensures the outcome is still measured on these patients

Reporting bias



- systematic differences between reported and unreported findings.
- E.g publication bias, more likely to report significant differences between intervention groups than non-significant differences.

Selective outcome reporting (Reporting bias)

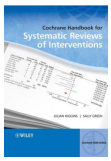
Low risk of bias

- The study protocol is available and all of the study's pre-specified (primary and secondary) outcomes that are of interest in the review have been reported in the pre-specified way
- The study protocol is not available but it is clear that the published reports include all expected outcomes

High risk of bias

- Not all of the study's pre-specified primary outcomes have been reported
- One or more primary outcomes is reported using measurements, analysis methods or subsets of the data (e.g. subscales) that were not pre-specified
- One or more reported primary outcomes were not pre-specified (unless clear justification for their reporting is provided, such as an unexpected adverse effect);
- outcomes of interest in the review are reported

Other biases



- Trial designs
  - carry-over in cross-over trials
  - recruitment bias in cluster-randomized trials
    - E.g participants may know already which group they have been allocated to because everyone in that "cluster" gets the same intervention.

Cochrane risk of bias table

Abstract

Objective To investigate the effectiveness of facilitated physical activity as an adjunctive treatment for adults with depression presenting in primary care.

Design Pragmatic, multicentre, two arm parallel randomised controlled trial.

Setting General practices in Bristol and Exeter.

Participants 361 adults aged 18-69 who had recently consulted their general practitioner with symptoms of depression. All those randomised had a diagnosis of an episode of depression as assessed by the clinical interview schedule-revised and a Beck depression inventory score of 14 or more.

Interventions In addition to usual care, intervention participants were offered up to three face to face sessions and 10 telephone calls with a trained physical activity facilitator over eight months. The intervention was based on theory and aimed to provide individually tailored support and encouragement to engage in physical activity.

Main outcome measures The primary outcome was self reported symptoms of depression, assessed with the Beck depression inventory at four months post-randomisation. Secondary outcomes included use of antidepressants and physical activity at the four, eight, and 12 month

−0.54 (95% confidence interval −3.06 to 1.99; P=0.68). Similarly, there was no evidence that the intervention group reported a change in mood by the eight and 12 month follow-up points. Nor was there evidence that the intervention reduced antidepressant use compared with usual care (adjusted odds ratio 0.63, 95% confidence interval 0.19 to 2.06; P=0.44) over the duration of the trial. However, participants allocated to the intervention group reported more physical activity during the follow-up period than those allocated to the usual care group (adjusted odds ratio 2.27, 95% confidence interval 1.32 to 3.89; P=0.003).

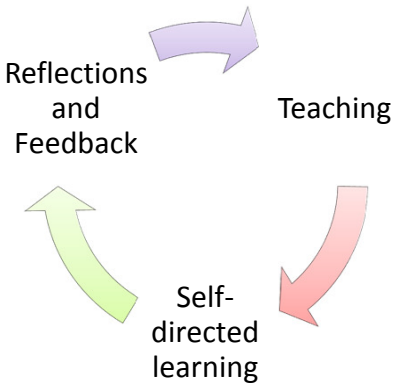
Conclusions The addition of a facilitated physical activity intervention to usual care did not improve depression outcome or reduce use of antidepressants compared with usual care alone.

Trial registration Current Controlled Trials ISRCTN16900744.

Introduction

Depression is one of the most common reasons for consulting a general practitioner within the United Kingdom, and its associated economic burden is considerable.[1] Although antidepressants are effective, many patients and healthcare professionals would like other options to be available as an alternative or adjunct to drug therapy.[2] Some evidence[3] shows

Teaching-Feedback cycle



Recruitment (selection bias)

- Were the subjects representative of the target population?
  - What were the inclusion & exclusion criteria?
  - Were they appropriate?
  - How/where were they recruited from?

- Methods Recruitment of participants and baseline assessment & Results 1st para

Allocation (selection bias)

- Were the groups comparable at the start?
  - "Table 1"
- Randomised appropriately?
- Allocation to group concealed beforehand?

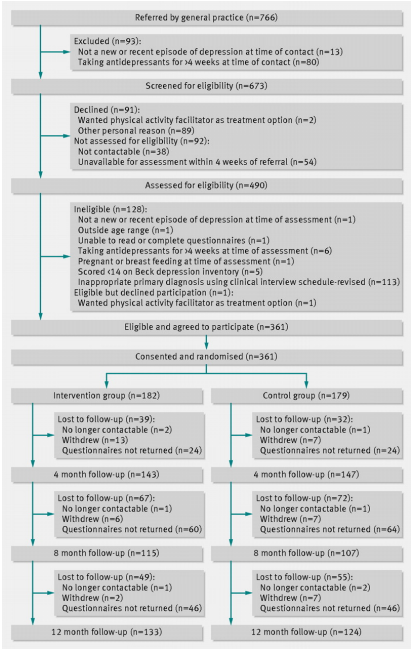
- Methods: Randomisation, concealment, and blinding and "Table 1"

Maintenance

- Were both groups comparable throughout the study?
  - Managed equally bar the intervention?
    - What was the intervention?
    - What was the comparator?
- Methods: Follow up and Intervention and comparator (usual care)

Adequate follow up? (Attrition bias)

- How many people were lost to f/u?
- Why were they lost to f/u?
- Did the researchers use an intention to treat (ITT) principle?
  - Once a participant is randomised, they should be analysed to the group they were assigned to
- Figure 1 and Statistical analysis



Measurement – blinding (Performance bias)

- Were the outcomes measured blindly by researchers and participants?
  - Double blinding (low risk of bias)
    - Subjects and investigators (outcome assessors) both unaware of allocation
  - Single blinded (moderate risk of bias)
    - Either subjects OR investigators (outcome assessors) unaware of allocation
  - No blinding (high risk of bias)
    - Subjects and investigators aware of allocation
- Methods: Randomisation, concealment, and blinding

P - values and CI

- P values
  - Measure of probability that a result is due to chance
  - The smaller the value (usually P<0.05) less likely due to chance
- Confidence intervals
  - Estimate of the range of values that are likely to include the real value
  - 95% chance of including the real value
  - Narrower the range>more reliable
  - If value does not cross 0 for a difference, or 1 for a ratio then pretty sure result is real (p<0.05)

Measurement - outcomes

- What were the outcomes?
  - Primary
  - Secondary
  - Were they appropriate?
- How were the results reported?
- Were they significant?

- Methods: Outcomes and Results

Instructions: This questionnaire consists of 21 groups of statements. Please read each group of statements carefully, and then pick out the **one statement** in each group that best describes the way you have been feeling during the **past two weeks, including today**. Circle the number beside the statement you have picked. If several statements in the group seem to apply equally well, circle the highest number for that group. Be sure that you do not choose more than one statement for any group, including Item 16 (Changes in Sleeping Pattern) or Item 18 (Changes in Appetite).

1. Sadness
0 I do not feel sad.
1 I feel sad much of the time.
2 I am sad all the time.
3 I am so sad or unhappy that I can't stand it.

2. Pessimism
0 I am not discouraged about my future.
1 I feel more discouraged about my future than I used to be.
2 I do not expect things to work out for me.
3 I feel my future is hopeless and will only get worse.

3. Past Failure
0 I do not feel like a failure.
1 I have failed more than I should have.
2 As I look back, I see a lot of failures.
3 I feel I am a total failure as a person.

4. Loss of Pleasure
0 I get as much pleasure as I ever did from the things I enjoy.
1 I don't enjoy things as much as I used to.
2 I get very little pleasure from the things I used to enjoy.
3 I can't get any pleasure from the things I used to enjoy.

5. Guilty Feelings
0 I don't feel particularly guilty.
1 I feel guilty over many things I have done or should have done.
2 I feel quite guilty most of the time.
3 I feel guilty all of the time.

6. Punishment Feelings
0 I don't feel I am being punished.
1 I feel I may be punished.
2 I expect to be punished.
3 I feel I am being punished.

7. Self-Dislike
0 I feel the same about myself as ever.
1 I have lost confidence in myself.
2 I am disappointed in myself.
3 I dislike myself.

8. Self-Criticalness
0 I don't criticize or blame myself more than usual.
1 I am more critical of myself than I used to be.
2 I criticize myself for all of my faults.
3 I blame myself for everything bad that happens.

9. Suicidal Thoughts or Wishes
0 I don't have any thoughts of killing myself.
1 I have thoughts of killing myself, but I would not carry them out.
2 I would like to kill myself.
3 I would kill myself if I had the chance.

10. Crying
0 I don't cry anymore than I used to.
1 I cry more than I used to.
2 I cry over every little thing.
3 I feel like crying, but I can't.

11. Agitation
0 I am no more restless or wound up than usual.
1 I feel more restless or wound up than usual.
2 I am so restless or agitated that it's hard to stay still.
3 I am so restless or agitated that I have to keep moving or doing something.

12. Loss of Interest
0 I have not lost interest in other people or activities.
1 I am less interested in other people or things than before.
2 I have lost most of my interest in other people or things.
3 It's hard to get interested in anything.

13. Indecisiveness
0 I make decisions about as well as ever.
1 I find it more difficult to make decisions than usual.
2 I have much greater difficulty in making decisions than I used to.
3 I have trouble making any decisions.

14. Worthlessness
0 I do not feel I am worthless.
1 I don't consider myself as worthwhile and useful as I used to.
2 I feel more worthless as compared to other people.
3 I feel utterly worthless.

15. Loss of Energy
0 I have as much energy as ever.
1 I have less energy than I used to have.
2 I don't have enough energy to do very much.
3 I don't have enough energy to do anything.

16. Changes in Sleeping Pattern
0 I have not experienced any change in my sleeping pattern.
1a I sleep somewhat more than usual.
1b I sleep somewhat less than usual.
2a I sleep a lot more than usual.
2b I sleep a lot less than usual.
3a I sleep most of the day.

17. Irritability
0 I am no more irritable than usual.
1 I am more irritable than usual.
2 I am much more irritable than usual.
3 I am irritable all the time.

18. Changes in Appetite
0 I have not experienced any change in my appetite.
1a My appetite is somewhat less than usual.
1b My appetite is somewhat greater than usual.
2a My appetite is much less than before.
2b My appetite is much greater than usual.
3a I have no appetite at all.
3b I crave food all the time.

19. Concentration Difficulty
0 I can concentrate as well as ever.
1 I can't concentrate as well as usual.
2 It's hard to keep my mind on anything for very long.
3 I find I can't concentrate on anything.

20. Tiredness or Fatigue
0 I am no more tired or fatigued than usual.
1 I get more tired or fatigued more easily than usual.
2 I am too tired or fatigued to do a lot of the things I used to do.
3 I am too tired or fatigued to do most of the things I used to do.

21. Loss of Interest in Sex
0 I have not noticed any recent change in my interest in sex.
1 I am less interested in sex than I used to be.
2 I am much less interested in sex now.
3 I have lost interest in sex completely.

Outcomes

	Measure	Narrative	Numerical
Primary outcome: short term symptoms of depression	Beck depression inventory score	no evidence that participants in the intervention group had a better outcome at four months than those in the usual care group	difference in mean score of −0.54 (95% confidence interval −3.06 to 1.99; P=0.68)
Secondary outcomes Longer term symptoms of depression	Beck depression inventory score	no evidence of a difference between the treatment groups over the duration of the study	difference in mean Beck depression inventory score −1.20,95% confidence interval−3.42 to 1.02;P=0.29
Anti-depressant use	participants reporting use of antidepressants	no evidence to suggest any difference between the groups at either the four month follow-up point or duration of trial	adjusted odds ratio 1.20, 95% confidence interval 0.69 to 2.08; P=0.52
Physical activity	self completion seven day recall diary	there was some evidence for a difference in reported physical activity between the groups at four months post-randomisation	adjusted odds ratio 1.58, 0.94 to 2.66; P=0.08)

Conclusions of the study

BMJ 2012;344:e2758 doi: 10.1136/bmj.e2758 (Published 6 June 2012)

What is already known on this topic

Depression is a leading contributor to disability in the United Kingdom and is associated with a decrement of health greater than many other chronic diseases

Many patients and healthcare professionals would like an effective and accessible non-drug treatment for depression

Numerous studies have reported the positive effects of physical activity but most of the current evidence originates from small non-clinical samples using interventions that are not practicable in healthcare settings

What this study adds

A physical activity intervention in addition to usual care did not improve symptoms of depression or reduce the use of antidepressants compared with usual care alone

The intervention increased self reported physical activity and this effect was sustained for 12 months

Clinicians and policy makers should alert people with depression that advice to increase physical activity will not increase their chances of recovery from depression

Re: Facilitated physical activity as a treatment for depressed adults: randomised controlled trial

6 June 2012

Great - another depressing headline

Those of you out there working tirelessly to get people 'enjoying' a more active lifestyle are, like me, unlikely to be overjoyed at today's headlines on the BBC website's health page.1 A nice example of bad PR in my opinion, particularly when you actually read the conclusions made by the authors of the headline source paper.2 I went a bit mad on twitter for an hour or so after I read the study but after calming down decided that a better way to get answers to my many questions would be via this letter. So, for me it would be useful to know the following:

1. How does the conclusion "advice and encouragement to increase physical activity is not an effective strategy for reducing symptoms of depression" translate to "Exercise 'no help for depression' research suggests"?1

2. Why does OR 1.58, 0.94 to 2.66 P = 0.08 translate to "some evidence" when OR of 0.66, 0.4 to 1.11 P = 0.12 translates to "no

BBC NEWS HEALTH

Exercise 'no help for depression' research suggests

By Branwen Jeffreys
Health correspondent, BBC News

Combining exercise with conventional treatments for depression does not improve recovery, research suggests.

In the NHS-funded study - published in the British Medical Journal - some patients were given help to boost their activity levels in addition to receiving therapy or anti-depressants.

After a year all 361 patients had fewer signs of depression, but there was no difference between the two groups.

Current guidelines suggest sufferers do up to three exercise sessions a week.

The National Institute for Health and Clinical Excellence (Nice) drew up that advice in 2004.

At present, the NHS can refer patients for a course of supervised exercise sessions

Exercise does little to help the symptoms of depression, new study finds

By SUZANNAH HILLS

PUBLISHED: 08:23, 6 June 2012 | UPDATED: 11:01, 8 June 2012

Comments (10) | Share +1 0 | Tweet 16

Exercise does little to help alleviate the symptoms of depression, a new study has found.

The findings contrast with current clinical guidance which recommends exercise to help those suffering from the mental illness that affects one in six adults in Britain at any one time.

But research published in the British Medical Journal suggests that doing a physical activity combined with usual treatment did not reduce symptoms of depression more than the treatment alone.

Odds ratio

- odds that an outcome will occur given a particular exposure, compared to the odds of the outcome occurring in the absence of that exposure
- Interpreting OR
  - OR=1 Exposure does not affect odds of outcome
  - OR>1 Exposure associated with higher odds of outcome
  - OR<1 Exposure associated with lower odds of outcome
- E.g.… OR = 1.46
  - Odds of having the outcome are 1.46 higher in the exposed group vs control group

Odds ratio

Outcome of interest

Exposure of interest

	+	-
+	a	b
-	c	d

$$OR = \frac{a/c}{b/d}$$

Relative Risk or Risk Ratio

- the risk of the event in one group divided by the risk of the event in the other group
- Interpreting RR
  - RR =1 Exposure does not affect risk of outcome
  - Is the treatment intended to prevent an undesirable outcome?
    - RR < 1Exposure reduces the risk of the event
    - RR > 1 Exposure increases the risk of the event (possible treatment harm, adverse events)
  - Is the treatment intended to promote an outcome? (e.g. disease remission)
    - RR < 1Exposure reduces the risk of the event (disease remission)
    - RR > 1 Exposure increases the risk of the event (disease remission)

E.g.… RR = 0.46

- Risk of getting the outcome with the exposure was 0.46 of that in the control group

RR v OR

- Often similar when event rate is low (<10%) or treatment effect is small (close to 1)
- As event rate increases (>10%)

Relative Risk or Risk Ratio

Outcome of interest

Exposure of interest	+	-
+	a	b
-	c	d

$$RR = \frac{a/(a+b)}{c/(c+d)}$$
